# mail

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from, Europe, America and south Asia, supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of "Quality Parts, Customers Priority, Honest Operation, and Considerate Service", our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip, ALPS, ROHM, Xilinx, Pulse, ON, Everlight and Freescale. Main products comprise IC, Modules, Potentiometer, IC Socket, Relay, Connector. Our parts cover such applications as commercial, industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

### ISO HIGH SIDE SMART POWER SOLID STATE RELAY

#### **Table 1. General Features**

| Туре | V <sub>DSS</sub> | R <sub>DS(on)</sub> | I <sub>n</sub> <sup>(1)</sup> | Vcc  |
|------|------------------|---------------------|-------------------------------|------|
| VN31 | 60 V             | 0.03 Ω              | 11.5 A                        | 26 V |

Note: 1. In= Nominal current according to ISO definition for high side automotive switch. The Nominal Current is the current at  $T_c = 85$  °C for battery voltage of 13V which produces a voltage drop of 0.5 V.

- MAXIMUM CONTINUOUS OUTPUT CURRENT (note 2): 31 A @ T<sub>c</sub>= 85°C
- 5V LOGIC LEVEL COMPATIBLE INPUT
- THERMAL SHUT-DOWN
- UNDER VOLTAGE PROTECTION
- OPEN DRAIN DIAGNOSTIC OUTPUT
- INDUCTIVE LOAD FAST DEMAGNETIZATION
- VERY LOW STAND-BY POWER DISSIPATION

Note: 2. The maximum continuous output current is the current at  $T_c = 85$  °C for a battery voltage of 13 V which does not activate self protection.

#### DESCRIPTION

The VN31 is a monolithic device made using STMicroelectronics VIPower Technology, intended for driving resistive or inductive loads with one side grounded.

Built-in thermal shut-down protects the chip from over temperature and short circuit.

The open drain diagnostic output indicates: open load in off state and in on state, output shorted to  $V_{CC}$  and overtemperature. Fast demagnetization of inductive loads is achieved by negative (-18V) load voltage at turn-off.

#### Figure 7. Switching Time Waveforms

#### FUNCTIONAL DESCRIPTION

The device has a diagnostic output which indicates open load conditions in off state as well as in on state, output shorted to  $V_{CC}$  and overtemperature. The truth table shows input, diagnostic and output voltage level in normal operation and in fault conditions. The output signals are processed by internal logic. The open load diagnostic output has a 5 ms filtering. The filter gives a continuous signal for the fault condition after an initial delay of about 5 ms. This means that a disconnection during normal operation, with a duration of less than 5 ms does not affect the status output. Equally, any re-connection of less than 5 ms during a disconnection duration does not affect the status output. No delay occur for the status to go low in case of overtemperature conditions. From the falling edge of the input signal the status output initially low in fault condition (over temperature or open load) will go back with a delay (tpovi)in case of overtemperature condition and a delay (tpol) in case of open load. These feature fully comply with International Standard Office (I.S.O.) requirement for automotive High Side Driver.

To protect the device against short circuit and over current conditions, the thermal protection turns the integrated Power MOS off at a minimum junction temperature of 140 °C. When the temperature returns to 125 °C the switch is automatically turned on again. In short circuit the protection reacts with virtually no delay, the sensor being located in the region of the die where the heat is generated. Driving inductive loads, an internal function of the device ensures the fast demagnetization with a typical voltage ( $V_{demag}$ ) of -18V.

This function allows to greatly reduce the power dissipation according to the formula:

where f = switching frequency and

V<sub>demag</sub> = demagnetization voltage

Based on this formula it is possible to know the value of inductance and/or current to avoid a thermal shut-down. The maximum inductance which causes the chip temperature to reach the

shut down temperature in a specific thermal environment, is infact a function of the load current for a fixed V<sub>CC</sub>, V<sub>demag</sub> and f.

#### PROTECTING THE DEVICE AGAIST LOAD DUMP - TEST PULSE 5

The device is able to withstand the test pulse No. 5 at level II (V<sub>s</sub> = 46.5V) according to the ISO T/R 7637/1 without any external component. This means that all functions of the device are performed as designed after exposure to disturbance at level II. The VN31 is able to withstand the test pulse No.5 at level III adding an external resistor of 150 ohm between pin 1 and ground plus a filter capacitor of 1000  $\mu$ F between pin 3 and ground (if R<sub>LOAD</sub>  $\leq$  20  $\Omega$ ).

#### PROTECTING THE DEVICE AGAINST REVERSE BATTERY

The simplest way to protect the device against a continuous reverse battery voltage (-26V) is to insert a Schottky diode between pin 1(GND) and ground, as shown in the typical application circuit (Figure 10).

The consequences of the voltage drop across this diode are as follows:

- If the input is pulled to power GND, a negative voltage of -V<sub>f</sub> is seen by the device. (V<sub>IL</sub>, V<sub>IH</sub> thresholds and V<sub>STAT</sub> are increased by V<sub>f</sub> with respect to power GND).
- The undervoltage shutdown level is increased by V<sub>f</sub>.

If there is no need for the control unit to handle external analog signals referred to the power GND, the best approach is to connect the reference potential of the control unit to node [1] (see application circuit in Figure 11), which becomes the common signal GND for the whole control board avoiding shift of  $V_{IH}$ ,  $V_{IL}$  and  $V_{STAT}$ . This solution allows the use of a standard diode.
