

Chipsmall Limited consists of a professional team with an average of over 10 year of expertise in the distribution of electronic components. Based in Hongkong, we have already established firm and mutual-benefit business relationships with customers from,Europe,America and south Asia,supplying obsolete and hard-to-find components to meet their specific needs.

With the principle of “Quality Parts,Customers Priority,Honest Operation,and Considerate Service”,our business mainly focus on the distribution of electronic components. Line cards we deal with include Microchip,ALPS,ROHM,Xilinx,Pulse,ON,Everlight and Freescale. Main products comprise IC,Modules,Potentiometer,IC Socket,Relay,Connector.Our parts cover such applications as commercial,industrial, and automotives areas.

We are looking forward to setting up business relationship with you and hope to provide you with the best service and solution. Let us make a better world for our industry!

## 16-BIT DIGITAL SIGNAL PROCESSORS

### FEATURES

Device	DSP ROM [KW]	OTP [KW]	DSP RAM [Words]	MIPS
Z89321	4		512	20
Z89371		4	512	20

- 0°C to 70°C Standard Temperature Range  
–40°C to +85°C Extended Temperature Range
- 4.5 to 5.5 Volt Operating Range

#### DSP Core

- 16-Bit Fixed Point DSP with 24-Bit ALU and Accumulator
- Single-Cycle Multiply and ALU Operations
- Six-Level Hardware Stack
- Six Data RAM Pointers and Sixteen Program Memory Pointers
- RISC Processor with 30 Instruction Types

### GENERAL DESCRIPTION

The Z893x1 products are high-performance Digital Signal Processors (DSPs) with a modified Harvard architecture featuring separate program and dual data memory banks. The design has been optimized for processing power with a minimum of silicon area.

The Z893x1 16/24-Bit architecture accommodates advanced signal processing algorithms. The operating performance and efficient architecture provide deterministic instruction execution. Compression, filtering, frequency detection, audio, voice detection/synthesis, and other vital algorithms can all be implemented.

Six data RAM pointers provide circular buffer capabilities and simultaneous dual operand fetching. Three vectored in-

Device	40-Pin DIP	44-Pin PLCC	44-Pin PQFP
Z89321	X	X	X
Z89371	X	X	X

#### Internal Peripherals

- 13-Bit General-Purpose Timer
- Dual Channel 8/16/64-Bit CODEC Interface with optional Hardware  $\mu$ -Law Compression

#### External Peripheral Interface

- 16-Bit Tri-Stated External Data Bus
- 3-Bit Latched External Address Bus
- Wait-State Generator
- Three Vectored Interrupts

errupts are complemented by a six-level stack. A 13-bit Timer is available for general-purpose use. A CODEC Interface allows high-speed transfer rates to accommodate digital audio and voice data. A dedicated Counter/Timer provides the necessary timing signals for the CODEC Interface.

The Z893x1 CODEC Interface is compatible with 8-bit PCM and 16/64-bit CODECs used in digital audio applications, and serial A/D and D/A converters. A Wait-State Generator is provided to accommodate slow external peripherals.

For prototypes, low volume, or special production runs, the Z89371 is a one-time programmable (OTP) device.

GENERAL DESCRIPTION (Continued)

**Note:** All signals with an overline are active Low. For example in RD/ $\overline{WR}$ , RD is active High and  $\overline{WR}$  is active Low.

The power connections follow the convention described below:

Connection	Circuit	Device
Power	V <sub>CC</sub>	V <sub>DD</sub>
Ground	GND	V <sub>SS</sub>

Figure 1. Z893x1 Functional Block Diagram

## PIN FUNCTIONS

**External Bus and External Registers.** The following is made to clarify naming conventions used in this specification. The external bus and external registers are “external”

to the DSP core, and are used to access internal and external peripherals.

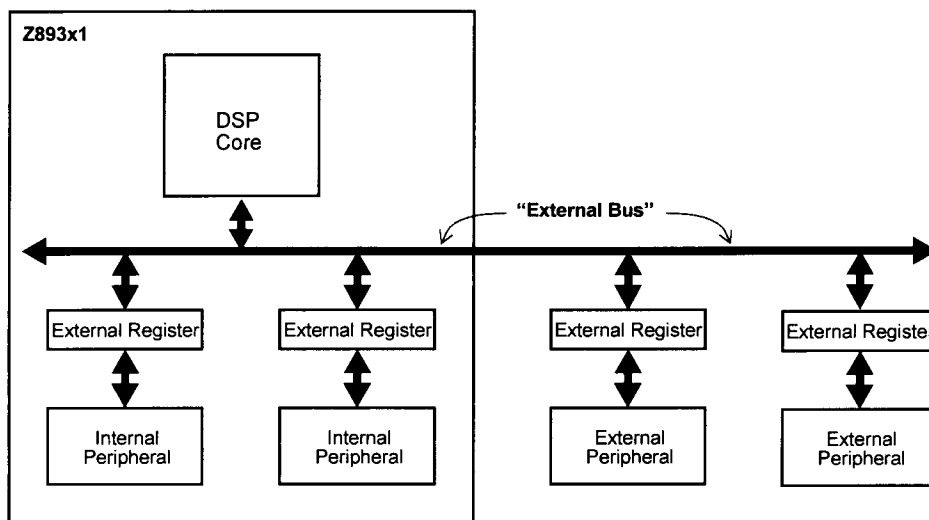

Figure 2. “External” Bus

**EA2–EA0.** External Address Bus (output). These pins control the user-defined register address output (latched). This bus is driven during both internal and external accesses. One of seven user-defined external registers is selected by the processor for reads or writes. External registers EXT0–EXT3 are always available to the user. External registers EXT4–EXT6 are used internally by the processor, or optionally by the user, if the pertinent internal peripherals are disabled. EXT7 is always reserved for use by the processor.

**ED15–ED0.** External Data Bus (input/output). These pins are the data bus for the user-defined external registers. The pins are normally tri-stated, except when these registers are specified as destination registers in a write instruction to an external peripheral. This bus uses the control signals RD/W $\overline{R}$ ,  $\overline{DS}$ , WAIT and the address pins EA2–EA0.

**Note:** The ED Bus was known as the EXT Bus in earlier versions of this document, and may be referred to as the EXT Bus, pins EXT15–EXT0, in other older related documents.

**$\overline{DS}$ .** Data Strobe (output). This pin provides the data strobe signal for the ED Bus. DS is active for transfers to/from external peripherals only.

**R $\overline{D}$ /W $\overline{R}$ .** Read/Write Select (output). This pin controls the data direction signal for the ED Bus. Data is available from the processor on ED15–ED0 when this signal and  $\overline{DS}$  are both Low.

**WAIT.** WAIT State (input). The wait signal is sampled at the rising edge of the clock with appropriate setup and hold times. A single wait-state can be generated internally by setting the appropriate bits in the wait state register. The user must drive this line if multiple wait states are required. This pin has an internal pull-down.

**HALT.** Halt State (input). This pin stops program execution. The processor continuously executes NOPs and the program counter remains at the same value when this pin is held High. This pin has an internal pull-down.

**INT0–INT2.** Interrupts (input, positive edge triggered). These pins control interrupt requests 0–2. Interrupts are generated on the rising edge of the input signal. The DSP

## PIN FUNCTIONS (Continued)

fetches the interrupt service routine starting addresses from the following program memory locations:

Device	INT0	INT1	INT2
Z89321/371	0FFFH	0FFEh	0FFDH
Z89391	FFFFH	FFFEh	FFFDH

The interrupt priority is INT0 = highest, INT2 = lowest. These pins have internal pull-downs.

---

**Note:** INT1 and INT2 pins are not available on the 40-pin DIP package.

---

**CLK Clock (input).** This pin is the clock circuit input.

**RESET.** Reset (input, active Low). This pin resets the processor. It pushes the contents of the Program Counter (PC) onto the stack and then fetches a new PC value from program memory address 0FFCH (or FFFCH for the Z89391) after the RESET signal is released. The Status register is set to all zeros. At power-up, RAM and other registers are undefined; however, they are left unchanged with subsequent

resets. RESET can be asserted asynchronously. If the rising edge of RESET meets prescribed setup conditions relative to the falling edge of the clock, the processor commences execution with a fixed number of clock cycles later. See the Timing Diagrams definitions for details.

**UI0, UI1.** User Input (input). These general-purpose input pins are directly tested by the conditional branch instructions. The pins can also be read as bits in the status register. These are asynchronous input signals that have no special clock synchronization requirements.

**UO0, UO1.** User Output (output). These general-purpose output pins reflect the value of two bits in the status register. These bits may be used to output data by writing to the status register.

---

**Note:** The value at the output pin is inverted from the value in the register.

---

The pins **SCLK, FS0, FS1, RXD** and **TXD** are described in the CODEC Interface section.

## ABSOLUTE MAXIMUM RATINGS

Symbol	Description	Min	Max	Units
$V_{DD}$	Supply voltage with respect to $V_{SS}$	-0.3	7.0	V
$T_{STG}$	Storage Temperature	-65	150	°C
$T_A$	Ambient Operating Temperature			
	"S" device	0	70	°C
	"E" device	-40	85	°C

Stresses greater than those listed under the Absolute Maximum Ratings may cause permanent damage to the device. This rating is a stress rating only. Operation of the device at any condition above those indicated in the operational sections of these specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## STANDARD TEST CONDITIONS

The characteristics listed below apply for standard test conditions as noted. All voltages are referenced to Ground.

Positive current  $I_{(+)}$  flows into the referenced pin.

Negative current  $I_{(-)}$  flows out of the referenced pin.

Figure 6. Test Load Diagram

## DC ELECTRICAL CHARACTERISTICS

Table 4.  $V_{DD} = 5V \pm 10\%$ ,  $T_A = 0^\circ C$  to  $+70^\circ C$  for "S" Temperature Range

Figure 13. Synchronous Reset Timing

## FUNCTIONAL DESCRIPTION

**Instruction Timing.** Most instructions are executed in one machine cycle. A multiplication or multiply/accumulate instruction requires a single cycle. Long immediate instructions (and Jump or Call instructions) are executed in two machine cycles. Specific instruction cycle times are described in the Instruction Description section.

**Multiply/Accumulate.** The multiplier can perform a 16-bit x 16-bit multiply (or multiply/accumulate) in one machine cycle using the Accumulator and/or both the X and Y inputs. The multiplier produces a 32-bit result; however, only the 24 most significant bits are saved for the next instruction or accumulation. For operations on very small numbers, where the least-significant bits are important, the data should first be scaled to avoid truncation errors.

Figure 14. Multiplier Block Diagram

All inputs to the multiplier should be fractional two's-complement, 16-bit binary numbers, putting them in the range  $[-1$  to  $0.9999695]$ . The result is in 24 bits, so the range is  $[-1$  to  $0.9999999]$ .

If 8000H is loaded into both the X and Y registers, the multiplication will produce an incorrect result. A positive one (+1) cannot be represented in fractional notation. The multiplier will actually yield the result  $8000H \times 8000H = 8000H$  ( $-1 \times -1 = -1$ ). The user should avoid this case to prevent erroneous results.

A shifter between the P Register and the Multiplier Unit Output can shift the data by three bits right or no shift.

**Data Bus Bank Switch.** There is a switch that connects the X Bus to the DDATA Bus that allows both the X and Y registers to be loaded with the same operand for a one cycle squaring operation. The switch is also used to read the X register.

**ALU.** The ALU has two input ports. One is connected to the output of the 24-bit Accumulator. The other input selects either the Multiplier Unit Output or the 16-bit DDATA bus (left-justified with zeros in the eight LSBs). The ALU performs arithmetic, logic, and shift operations.

Figure 15. ALU Block Diagram

**Hardware Stack.** A six-level hardware stack is connected to the DDATA bus to hold subroutine return addresses or data. The Call instruction pushes PC+2 onto the stack, and the RET instruction pops the contents of the stack to the PC.

**User Inputs and Outputs.** The Z893x1 has two user inputs, UI0 and UI1, and two user outputs, UO0 and UO1. The input pins are connected directly to status register bits S10 and S11. These bits can be read, or they can be used as a condition code in any conditional instruction. The output pins are connected directly to status register bits S5 and S6, and can be written to.

**Note:** The value at the output pin is inverted from the value in the register.

**Interrupts.** The Z893x1 has three positive edge-triggered interrupt inputs. An interrupt is serviced at the end of an instruction execution. Two machine cycles are required to enter an interrupt instruction sequence. The PC is pushed onto the stack. At the end of the interrupt service routine, a RET instruction is used to pop the stack into the PC. The priority of the interrupts is INT0 = highest, INT2 = lowest. When those peripherals are enabled, INT1 is dedicated to the CODEC Interface and INT2 is dedicated to the 13-bit timer.

The Set-Interrupt-Enable-Flag (SIEF) instruction enables the interrupts. Interrupts are automatically disabled when entering an interrupt service routine. Before exiting an interrupt service routine, the SIEF instruction can be used to re-enable interrupts.

**Registers.** The Z893x1 has 19 internal registers and up to seven user-defined 16-bit external registers (EXT0–EXT6). The external register address space for EXT4–EXT6 is used by the Z893x1 internal peripherals. Disabling a peripheral allows access to these addresses for general-purpose use.

**External Register Usage.** The external registers EXT0–EXT6 are accessed using the External Address Bus EA2–EA0, the External Data Bus (ED Bus) ED15–ED0, and control signals  $\overline{DS}$ , WAIT, and RD/ $\overline{WR}$ . These registers provide a convenient data transfer capability with external peripherals. Data transfers can be performed in a single-cycle. An internal Wait-State generator is provided to accommodate slower external peripherals. A single wait state can be implemented through control register EXT7–2. For ad-

ditional wait states, the WAIT pin can be used. The WAIT pin is monitored only during execution of a read or write instruction to external peripherals on the ED bus.

**Wait-State Generator.** An internal Wait-State generator is provided to accommodate slow external peripherals. A single Wait-State can be implemented through a control register. For additional states, a dedicated pin (WAIT) can be held Low. The WAIT pin is monitored only during execution of a read or write instruction to external peripherals (ED bus).

**CODEC Interface.** The CODEC Interface provides the necessary control signals for transmission of CODEC information to/from the processor. The CODEC Interface accommodates external 8-bit PCM or 16/64-bit linear CODECs. The CODEC Interface can also be used with external A/D and D/A converters. The interface can also be used as a high-speed serial port.

**$\mu$ -Law Compression.** The CODEC Interface provides optional hardware  $\mu$ -Law compression from 13-bit format to 8-bit format. Decompression is performed in software using a 128-word lookup table.

**Timers.** Two programmable timers, a general purpose 13-bit Timer, and a dedicated 12-bit Counter/Timer are provided to support the CODEC Interface. The 13-bit Timer can be operated in either continuous or one-shot mode. If the CODEC Interface is not enabled, its 12-bit Counter/Timer is also available for general-purpose use.

## MEMORY MAP

**Program Memory.** Programs of up to 4K words can be masked into internal ROM (Z89321) or programmed into an OTP (Z89371). Four locations are dedicated to the vector addresses for the three interrupts (0FFDH–0FFFH) and the starting address following a  $\overline{\text{RESET}}$  (0FFCH). Internal ROM is mapped from 0000H to 0FFFH, and the highest location for program instructions is 0FFBH.

**Internal Data RAM.** All Z893x1 family members have internal 512 x 16-bit data RAM organized as two banks of 256 x 16-bit words each (RAM0 and RAM1). The three addressing modes available to access the data RAM are direct addressing, short form direct, and register indirect.

The contents of both data RAM banks can be read simultaneously and loaded into the X and Y inputs of the multiplier during a multiply instruction.

The addresses for each data RAM bank are:

0–255 (0000H–00FFH) for RAM0  
256–511 (0100H–01FFH) for RAM1

**Data RAM Pointers.** In register indirect, each data RAM bank is addressed by one of three data RAM address pointers:

$P_n:b$ , where  
 $n$  = pointer number = 0, 1, or 2  
 $b$  = bank = 0 or 1,

thus,

P0:0, P1:0, P2:0 for RAM0  
P0:1, P1:1, P2:1 for RAM1

In auto-increment, loop-increment, and loop-decrement indirect addressing, the pointer is automatically modified.

The data RAM pointers, which may be read or written directly, are 8-bit registers connected to the lower byte of the internal 16-bit DDATA Bus.

**Program Memory Pointers.** The first 16 locations of each data RAM bank can be used as pointers to locations in Program Memory. These locations can be an efficient way to address coefficients. The programmer selects a pointer location using two bits in the status register and two bits in the operand. At any one time, there are eight usable pointers, four per bank, and the four pointers are in consecutive locations.

$D_n:b$ , where  
 $n$  = pointer number = 0, 1, 2, or 3  
 $b$  = bank = 0 or 1,

thus,

D0:0, D1:0, D2:0, D3:0 for RAM0  
D0:1, D1:1, D2:1, D3:1 for RAM1

For example, if  $S_3/S_4 = 01$  in the status register, then D0:0/D1:0/D2:0/D3:0 refer to register locations 4/5/6/7 in data RAM Bank 0.

Figure 16. Memory Map

## REGISTERS

The internal registers are defined in Table 6 below:

**Table 6. Register Definitions**

Register	Definition
X	Multiplier X Input, 16-bits
Y	Multiplier Y Input, 16-bits
P	Multiplier Output, 24-bits
A	Accumulator, 24-bits
Pn:b	Six Data RAM Pointers, 8-bits each
PC	Program Counter, 16-bits
SR	Status Register, 16-bits
EXT4	13-bit Timer Configuration Register
EXT5-1	CODEC Interface Channel 0 Data
EXT5-2	CODEC Interface Channel 0 Data
EXT6-1	CODEC Interface Channel 1 Data
EXT6-2	CODEC Interface Channel 1 Data
EXT7-1	CODEC Interface Configuration Register
EXT7-2	Wait-State Generator and CODEC Interface Configuration Register

**Note:** The loading and reading of the three pairs of CODEC Interface registers (EXT5-1,2 EXT6-1,2 and EXT7-1,2) are described in the CODEC Interface section.

**X** and **Y** are two 16-bit input registers for the multiplier. These registers can be utilized as temporary registers when the multiplier is not being used.

**P** holds the result of multiplications and is read-only.

**A** is a 24-bit Accumulator. The output of the ALU is sent to this register. When 16-bit data is transferred into this register, it is placed into the 16 MSBs, and the least significant eight bits are set to zero. Only the upper 16 bits are transferred to the destination register when the Accumulator is selected as a source register in transfer instructions.

**Pn:b** are the pointer registers for accessing data RAM where  $n = 0, 1, \text{ or } 2$ , and  $b = 0 \text{ or } 1$ . These registers can perform either a direct read or write function, and each can point to locations in data RAM.

**PC** is the Program Counter. Any instruction which may modify this register requires two clock cycles.

**SR** is the status register. It contains the ALU status and processor control bits (Table 7).

**Table 7. Status Register Bit Functions**

SR Bit	Function	Read/Write
S15 (N)	ALU Negative	RO
S14 (OV)	ALU Overflow	RO
S13 (Z)	ALU Zero	RO
S12 (L)	Carry	RO
S11 (UI1)	User Input 1	RO
S10 (UI0)	User Input 0	RO
S9 (SH3)	MPY Output Arithmetically Shifted Right by Three Bits	R/W
S8 (OP)	Overflow Protection	R/W
S7 (IE)	Interrupt Enable	R/W
S6 (UO1)	User Output 1	R/W
S5 (UO0)	User Output 0	R/W
S4-S3	"Short Form Direct" bits	R/W
S2-S0 (RPL)	RAM Pointer Loop Size	R/W

**Note:** RO = read only, RW = read/write. The status register can always be read in its entirety.

S15-S12 are set/reset by the ALU after an operation.

S11-S10 are set/reset by the user inputs.

If S9 is set, and a multiply/shift option is used, the shifter shifts the result three bits right. This feature allows the data to be scaled and prevents overflows.

If S8 is set, the hardware clamps at maximum positive or negative values instead of overflowing.

S7 enables interrupts.

S6-S0 are control bits.

REGISTERS (Continued)

Table 8. RPL Description

S2	S1	S0	Loop Size
0	0	0	256
0	0	1	2
0	1	0	4
0	1	1	8
1	0	0	16
1	0	1	32
1	1	0	64
1	1	1	128

The following are not actually registers; however, they have a read/write function that acts primarily the same way as the hardware registers do on the chip:

Register	Register Definition
BUS	DDATA Bus
Dn:b	Program Memory Pointers
EXTn	External Registers

**BUS** is a read-only register which, when accessed, returns the contents of the D-Bus. BUS is used for emulation only.

**Dn:b** refers to locations in RAM that can be used as a pointer to locations in program memory. These locations make the Z89321/371 capable for coefficient addressing. The programmer decides which location to choose from based on two bits in the status register and two bits in the operand; only the lower 16 possible locations in RAM can be specified. At any one time, there are eight usable pointers, four per bank, and the four pointer are in consecutive locations in RAM. For example, if S3/S4=1 in the status register, then D0:0/D1:0/D2:0/D3:0 refer to register locations 4/5/6/7 in RAM Bank 0.

**Note:** When the data pointers are being written to, a number is actually being loaded to Data RAM. In effect, these data pointers can be used as a limited method for writing to RAM.

**EXT0–EXT3** are used to map external peripherals into the address space of the processor.

**Note:** The actual register RAM does not exist on the chip, but would exist as part of the external device (such as an A/D result latch). The External Address Bus, EA2–EA0, the External Data Bus, ED15–ED0 and the control signals  $\overline{DS}$ , WAIT and RD/ $\overline{WR}$ , are used to access external peripherals.

**EXT4** is used by the 13-bit Timer. If the Timer is disabled, then this address can be used to access an external peripheral on the External Data Bus.

**EXT5** and **EXT6** are used by the CODEC Interface channels 0 and 1 respectively. If a CODEC channel is disabled, the corresponding address can be used to access an external peripheral.

**EXT7** is used to program wait states for EXT0–EXT6, and is not available for accessing an external peripheral.

If both the Timer and CODEC Interface are disabled, there are 7 addresses available to access external peripherals.

If both the Timer and CODEC Interface are enabled, there are 4 addresses available to access external peripherals.

Figure 17. Status Register

## PERIPHERAL OPERATION

### Overview

The peripherals for the Z893x1 family consist of a general purpose 13-bit Timer and a dual channel CODEC Interface.

The CODEC Interface contains its own 12-bit Counter/Timer. When the CODEC Interface is disabled, the Counter/Timer is available for general purpose use.

The output of the 12-bit Counter/Timer can also be linked with the input of the 13-bit Timer for extended timing. See the EXT4 and EXT7 register definitions for more information and examples.

### Enabling and Disabling Peripherals

At power on, and after a  $\overline{\text{RESET}}$ , the 13-bit general purpose Timer is enabled, but count operation is disabled. See the EXT4 register definition for more information concerning the operation of the Timer. While the Timer is enabled, it uses INT2 to signal a time out. When the Timer is disabled, EXT4 and INT2 are available for use by an external peripheral.

At power on, and after a  $\overline{\text{RESET}}$ , the CODEC Interface is disabled. See EXT5, EXT6, and EXT7 register definitions for more information concerning the operation of the CODEC Interface. While the CODEC Interface is enabled, it uses INT1 to signal the end of a frame. When a CODEC Interface channel is disabled, its corresponding EXT address is available. When both channels are disabled, EXT5, EXT6, and INT1 are available for use by an external peripheral. EXT7 is always reserved for internal use.

If an internal peripheral is enabled, the External Bus data and data strobe signals for the corresponding register address are not available on the External Bus (internal peripheral data transfers are processed internally).

### Interrupts

The Z893x1 interrupts are:

INT0	General-Purpose Use
INT1	CODEC Interface (when enabled), or else User
INT2	Timer (when enabled), or else User

## 13-BIT GENERAL PURPOSE TIMER

The General-Purpose Timer can be enabled or disabled. At power-on or  $\overline{\text{RESET}}$ , the counter is enabled. When the Timer is disabled, it can only be re-enabled by another  $\overline{\text{RESET}}$ . The Timer operates in a continuous or one-shot mode, and can be stopped. The Timer utilizes a 13-bit down-counter.

**Continuous Mode** With a load instruction, the user sets the Timer to run the mode, selects the clock source, and loads a non-zero count value:

1. When the down-counter reaches zero, an interrupt is generated on INT2,
2. The non-zero count value is automatically reloaded into the down-counter,
3. The process continues at step #1.

**One-Shot Mode** With a load instruction, the user sets the Timer to run the mode, selects the clock source, and loads a non-zero count value:

4. When the down-counter reaches zero, an interrupt is generated on INT2,
5. The user interrupt service routine must load a zero value into the Count Operation bit (D14 of EXT4),
6. The process stops.

**Timing Intervals** If the Timer clock source is CLK/2:

$$\text{Time Interval} = (\text{count value}) \times (2/\text{CLK})$$

$$\text{Timer Frequency} = (\text{CLK}/2) / (\text{count value})$$

where CLK denotes the system clock frequency.

**Extended Timing Intervals** The Timer interval can be extended beyond 13-bits by using the Timer in conjunction with the CODEC Interface Counter/Timer. The count is thus extended to a maximum of 25 bits:

- 12-bits from the CODEC counter/timer
- 13-bits from the Timer

If the Timer clock source is the CODEC counter output:

$$\text{Time Interval} = (\text{Timer count value}) \times (\text{CODEC counter/timer period})$$

$$\text{Timer Freq.} = (\text{CODEC counter/timer freq.}) \div (\text{Timer count value})$$

**Timer Interrupt Behavior** The following clarifies the behavior of the Timer interrupt:

- While the Timer is enabled, it utilizes the INT2 service routine address.
- The Timer is enabled after  $\overline{\text{RESET}}$ ; however, the Timer is in stop mode.
- The INT2 pin has an internal pull-down.
- When the Timer is in run mode, it generates an interrupt each time it counts down to zero.
- When the Timer is disabled, INT2 can be controlled by an external peripheral.

---

**Note:** If the Timer is to be disabled, and an external peripheral is driving INT2, it should hold INT2 High while the Timer is being disabled.

---

Figure 18. Timer Register EXT4

## CODEC INTERFACE

### Overview

The CODEC Interface not only supports a variety of external 8-bit, 16-bit linear, 64-bit sigma-delta stereo CODECs, and external A/D and D/A Converters, but the interface can also be used as a general purpose high-speed serial port. The CODEC Interface includes optional hardware  $\mu$ -Law compression. The CODEC Interface is designed to support both Half-Duplex and Full-Duplex operation. The CODEC In-

terface is designed to operate in master mode only. The CODEC Interface generates a serial clock and two Frame Sync signals, which allows for two channels of data.

### Hardware

The CODEC Interface hardware uses six 16-bit registers,  $\mu$ -Law compression logic, and general-purpose control logic to control transfers to/from the appropriate registers.

Figure 19. CODEC Interface Block Diagram

### CODEC Interface Control Signals

**SCLK.** Serial Clock (output). This pin provides the clock signal for operating the external CODEC. A 4-bit prescaler is used to divide down the system clock (CLK) to produce the desired output frequency of SCLK. An internal divide-by-two is performed on CLK before passing it to the SCLK prescaler:

$$\text{SCLK} = (\text{CLK}/2) \div \text{PS}$$

where PS = 2's complement of the 4-bit Pre-Scaler value (PS is an up-counter).

**TXD.** Serial Output Data (output). This pin provides 8, 16, and 64-bit data transfers. Each bit is clocked out of the processor by the rising edge of SCLK, with the MSB transmitted first.

**RXD.** Serial Input Data (input). This pin provides 8, 16, and 64-bit data transfers. Each bit is clocked into the processor by the falling edge of SCLK, with the MSB received first.

**FS0, FS1.** Frame Sync 0 and Frame Sync 1 (output). These pins are used to mark data transfer/receive frames. The rising and falling edge of the Frame Sync signals indicate the beginning and the end of each serial data transmission.

### CODEC Interface Interrupt Behavior

When the transmission of serial data is completed, the CODEC Interface generates an internal interrupt which vectors to the INT1 service routine address. This interrupt is coincident with the falling edge of FS1. The following clarifies the behavior of the CODEC Interface interrupt:

- While the CODEC Interface is enabled, it utilizes the INT1 service routine address.
- The CODEC Interface will be disabled after  $\overline{\text{RESET}}$ .
- The INT1 pin has an internal pull-down.
- If INT1 is tied High, the CODEC Interface generates an interrupt at the end of each frame transfer.
- If INT1 is not connected, or tied Low, the CODEC Interface not only generates an interrupt when first enabled, but generates an interrupt at the end of each frame transfer.
- When the CODEC Interface is disabled, INT1 can be controlled by an external peripheral.

**Note:** In single channel applications, use Channel 1 because INT1 coincides with FS1, not FS0.

### Registers

The CODEC Interface registers (EXT5, EXT6 and EXT7) each act as a 2-deep FIFO. See the CODEC Interface Block Diagram for more information, Figure 19. Two operations may be required for some data transfers.

**EXT5 and EXT6.** The CODEC Interface constantly transfers and receives data during normal operation. The reading of receive data, and the writing of transmit data, are interleaved.

An example of Channel 1 operation in 8 or 16-bit mode, where one can wait for the input data, is as follows:

LD<dest>, EXT6	; Read previous input data from EXT6-1
LD EXT6, <xmit data>	; Push current data from EXT6-2 to EXT6-1 ; Load EXT6-2 with data to be transmitted

To obtain the input data as soon as it arrives, and extra instruction is required:

LD EXT6, <anything>	; Push current input data from EXT6-2 to EXT6-1
LD<test>, EXT6	; Read current input data from EXT6-1
LD EXT6, <xmit data>	; Load EXT6-2 with data to be transmitted

For 64-bit mode, one can use the following code sequence:

LD <Ch. 0 MSW input dest>	; Get MSW of Ch. 0 input EXT5
LD <Ch. 1 MSW input dest>	; Get MSW of Ch 1 input EXT6
LD EXT5, <Ch. 0 MSW output data>	; Move LSB of Ch. 0 input and Load MSW of output
LD EXT6, <Ch. 1 MSW output data>	; Move LSB of Ch. 1 input and Load MSW of output
LD<Ch. 0 LSW input test>, EXT5	; Get LSW of Ch. 0 input EXT5
LD<Ch. 1 LSW input test>, EXT6	; Get LSW of Ch. 1 input EXT6
LD EXT5, <Ch. 0 LSW output data>	; Load LSW of Ch. 0 output
LD EXT6, <Ch. 1 LSW output data>	; Load LSW of Ch. 1 output

**Note:** EXT# denotes EXT5 or EXT6.

In the 8 and 16-bit modes, EXT5-2 and EXT6-2 are the shift registers for Channel 0 and Channel 1, respectively. In 8-bit mode, the 8-bits reside in the least significant byte for both transmit and receive. In 64-bit mode, the output/input order is EXT 5-1 first, followed by EXT5-2, EXT6-1, and finally by EXT6-2. In all modes, the MSB is shifted out/in first.

Channel 0 uses FS0, EXT5-1, and EXT5-2. Channel 1 uses FS1, EXT6-1, and EXT6-2.

**EXT7.** This register contains the configuration information for the CODEC Interface and the Wait-State Generator. In normal operation, the user writes configuration data for EXT7-1 followed by configuration data for EXT7-2.

Write EXT7 LD EXT7, <config data1>	; Move data to 7-2
LD EXT7, <config data2>	; Move data to 7-1
